Background

The recently signed COP 21 Paris Agreement calls for all nations to curb their CO2 emissions with the goal of keeping the global temperature rise this century to well below 2°C above pre-industrial levels (and striving to limit the increase to 1.5°C). The agreement assumes that the temperature will stabilize after the target is met. Unfortunately the planning does not appear to have taken into account the additional warming from natural causes (feedbacks) stemming from a warming planet. These include decreased albedo from the melting of summer-time ice in the Arctic Ocean, the reduced snow cover in the Northern Hemisphere, etc., and increased greenhouse gas emissions (primarily CO2 and methane) from peat bogs, thawing permafrost, etc.¹.

Radiative Forcing Computations

By estimating what the effective radiative forcings (ERF) of the major components of the climate system will be in 2100 it is possible to also estimate the resulting temperature increase based on an expected value for climate sensitivity. One can then determine if it is possible to meet the temperature goal of the Paris agreement through an aggressive emissions reduction effort with net-zero greenhouse gas emissions by 2060:

	ERF (\	N/m-2)	
#	2060	2100	Radiative Forcing Components
	Anthr	opogenic	c changes from 1870 - 2011
1	2.29	2.29	ERF in 2011 (IPCC) ²
	Anthr	opogenic	c changes from 2012 to 2100
2	0.41	0.65	Due to the reduction of aerosols and precursors (IPCC AR5: total of -0.82 in 2011, mostly due to the burning of fossil fuels; for 2060, 50% of the value is used; for 2100, 80% of the value is used) ²
3	0.80	0.80	Due to 1240 GTCO2 of CO2 emissions from an aggressive emission reduction scenario (emissions peak in 2025 and go to zero in 2055, resulting in increasing atmospheric CO2 by about 72 PPM)
4	-	-0.37	Due to the reduction of atmospheric concentrations of CH4, N2O, and halocarbons
	0.19		(IPCC RCP 2.6: -0.37 in 2100; for 2060, $\frac{1}{2}$ the estimated value is used) ³
5	??	??	Other – land use changes, atmospheric changes, etc.
	Additi	ons from	natural feedbacks ⁴ (represents the equivalent of about 1,700 GTCO2 in 2100)
6	0.14	0.25	Arctic Ocean - linear change in Arctic Ocean sea ice extent
7	0.12	0.18	Retreating snowline - linear change in Northern Hemisphere snow cover extent
8	0.06	0.32	Permafrost thawing (for 2060, 20% of the 120 GTC expected by 2100 (88 GTCO2, or 5 PPM CO2); for 2100, 440 GTCO2 or 25.5 PPM CO2)
9	0.14	0.27	Peatlands and Peat Bogs (4 GTCO2 per year: for 2060, for 50 years – 200 GTCO2, or 11 PPM; for 2100, 90 years – 360 GTCO2 or 21 PPM)
10	??	??	Other – methyl hydrates, forests, soils, etc.
	Total	Changes	in ERF
	3.81	4.43	Total Change in ERF from preindustrial times
	Estima	ated tem	perature increase for an energy imbalance of 0.7 w/m-2 and a climate sensitivity = 3.0 $^{\circ}C^{5}$
	2.4°	3.0°C	Expected temperature increase ⁶
	С		
	Estima	ated equi	ilibrium temperature change for a climate sensitivity of 3.0 °C ⁵ for a doubling of CO2 PPM
	3.1°	3.9°C	Equilibrium temperature increase ⁶
	C		

Table 1. Radiative forcing of the major components of the climate system for 2060 and 2100

If the climate sensitivity is 3⁵, the ERF for 2100 needs to be about 2.7 W/m-2 in order to limit the temperature increase to 2°C. The above analysis shows that the goals of the COP 21 Paris Agreement can only be met by capturing and sequestering enough CO2 to reduce the projected ERF in 2100 by about 1.7 W/m-2. This would require reducing the atmospheric CO2 concentration by about 180 PPM, or 3,100 GTCO2.

Expected Costs

Since the additions from the natural feedbacks are so large (being responsible for almost one-fourth of the total temperature increase in 2100), the Earth's atmosphere will continue to warm long after anthropogenic greenhouse gas emissions are reduced to zero. Unless these natural feedbacks can either be reduced to zero or compensated for (by annually removing an equivalent amount or carbon dioxide from the atmosphere), eliminating all anthropogenic emissions will not be sufficient to meet the IPCC's goals. Our global warming goal should really be to keep the Earth's temperature low enough so that we can afford to offset (e.g., sequester) the equivalent emissions from the global warming feedbacks - otherwise the Earth will eventfully warm enough to cause catastrophic climate change.

To get a ballpark estimate of the economic challenge, cost estimates for three scenarios in which the net anthropogenic emissions match the IPCC budget can easily be made:

	(Emissions in GTCO2)	No sequestration of	Sequestration of equivalent	Remove enough CO2
		equivalent CO2 from	CO2 from feedbacks	(1,600 GTCO2) to
		feedbacks		eliminate feedbacks
1	Total Emissions over budget	2120	2120	2120
2	CO2 Sequestered	420 (to meet IPCC budget)	2120	2120+ 1600
3	CO2e not sequestered	1700 (from feedbacks)	0	0
4	Sequestration Costs (T\$)	21	200	370
5	2100 ERF from feedbacks -	1.28	0	-1.08 (=2.6-1.52)
	extra CO2 removed			
6	Total ERF (W/m-2)	3.88 (=2.6+1.28)	2.6	1.52 (ERF for 1°C)
7	Equilibrium Temperature (°C)	3.2	1.9	1.0

Table 2 – Equilibrium Temperature Increase for Various Amount of CO2 Sequestration

The above estimates are based on the following parameters and assumptions:

1	1240	
		were about 34 GTCO2; if they increase annually by 2% until 2025 and then decline by 1.5 GTCO2 annually,
		there will be net zero emissions after 2055 and the total emissions will be about 1240 GTCO2)
2	180	Emissions (GTCO2)after 2055 that will need to be sequestered if annual emissions are about 4 GTCO2 ⁶
3	1,000	The IPCC post-2011 CO2 budget(GTCO2) for a 66% chance of limiting the temperature increase to 2°C ⁷
4	1,700	GTCO2 equivalent emissions from global warming feedbacks for a temperature increase of 2°C ⁴
5	3	The climate sensitivity to CO2 from a doubling of atmospheric CO2 ⁸
6	50	Per-ton cost (\$) of capturing and sequestering CO2 for CCS (anthropogenic emissions only ⁹
7	100	Per-ton cost (\$) of capturing and sequestering CO2 for direct air capture (DAC) ⁹
8	2.6	Effective radiative forcing (W/m-2) for a 1.9°C temperature increase and a climate sensitivity of 3 ¹⁰
Tal		arometers for Ballaark Estimate of CO2 Sequestration Costs Based on Amount of CO2 Sequestared

Table 3 – Parameters for Ballpark Estimate of CO2 Sequestration Costs Based on Amount of CO2 Sequestered

If anthropogenic emissions are in line with the UNFCCC budget and if the UNFCCC budget would result in a 2°C temperature increase, we can expect a temperature increase over 3°C for a modest cost. If we also remove CO2 from the atmosphere that is equivalent to the global warming feedbacks we can limit the temperature to 2°C for a cost of about \$200 Trillion, but the planet will continue to warm unless we spend another \$1.5 Trillion per year to offset the feedbacks of roughly 15 GTCO2. Since global warming feedbacks are already significant¹⁰ with a temperature increase of only about 1.1°C, it would

seem that we'd be lucky to eliminate the feedbacks with a temperature increase of only 1°C, which would cost over \$370 Trillion.

The prevailing assumption is that we will be willing (and able) to spend whatever it costs to keep meet the temperature target because anything more than that will likely be disastrous for our civilization. Giving up on that goal is then equivalent to condemning future generations to a planet that is inhospitable to civilization as we know it, and this may be the reason that very few people openly acknowledge our predicament. But a closer look expected costs (likely around \$370 Trillion this century if we can significantly reduce the expected cost of carbon dioxide removal to \$100/ton of CO2 for direct air capture) shows that we have a very daunting (and almost certainly insurmountable) problem.

Conclusions

- We can already expect about a 2°C temperature increase based on the greenhouse gases currently in the atmosphere (assuming emissions from burning coal are eliminated)^{11,12}
- There will be significant future anthropogenic greenhouse gas emissions for any realistic mitigation scenario
- Global warming feedbacks are already significant¹⁰
- There will be both significant future natural greenhouse gas emissions and significant albedo changes from the feedbacks from a warming world⁴
- Widespread thawing of the permafrost could start when the global temperature increases by 1.5°C¹³
- If only a small fraction of Arctic carbon is released into the atmosphere the result could be catastrophic¹⁴
- The costs of removing CO2 from the atmosphere at the scale and speed required to limit the temperate increase in 2100 to 2°C are prohibitive (see above analysis)
- Most climate change damage will happen before the two-degree warming threshold¹⁵
- Once the temperature increase is over 3°C (and possibly over 1.5°C), the feedbacks from the global warming will likely drive the temperature increase to well over 4°C, resulting in a planet that is not hospitable to civilization as we know it
- Long-term sea level rise will exceed 40 feet¹⁶
- Ocean acidification will be catastrophic¹⁷

It is almost impossible to see how we can prevent very serious climate disruption. We should not give up hope on solving climate change as it is always possible that some technological "miracle" may be discovered. But the prudent thing to do is to assume that very serious climate disruption will occur well before 2100. We then have two main choices – we can either (1) use albedo modification to reduce the Earth's average temperature (in order to prevent the natural emissions and albedo changes from global warming feedbacks), or (2) start planning for catastrophic climate change. If we really want human civilization to survive for at least another thousand years then the sooner we can start having realistic conversations about our likely future the greater the chances of survival will be.

Carbon Dioxide Removal (CDR) Costs

9

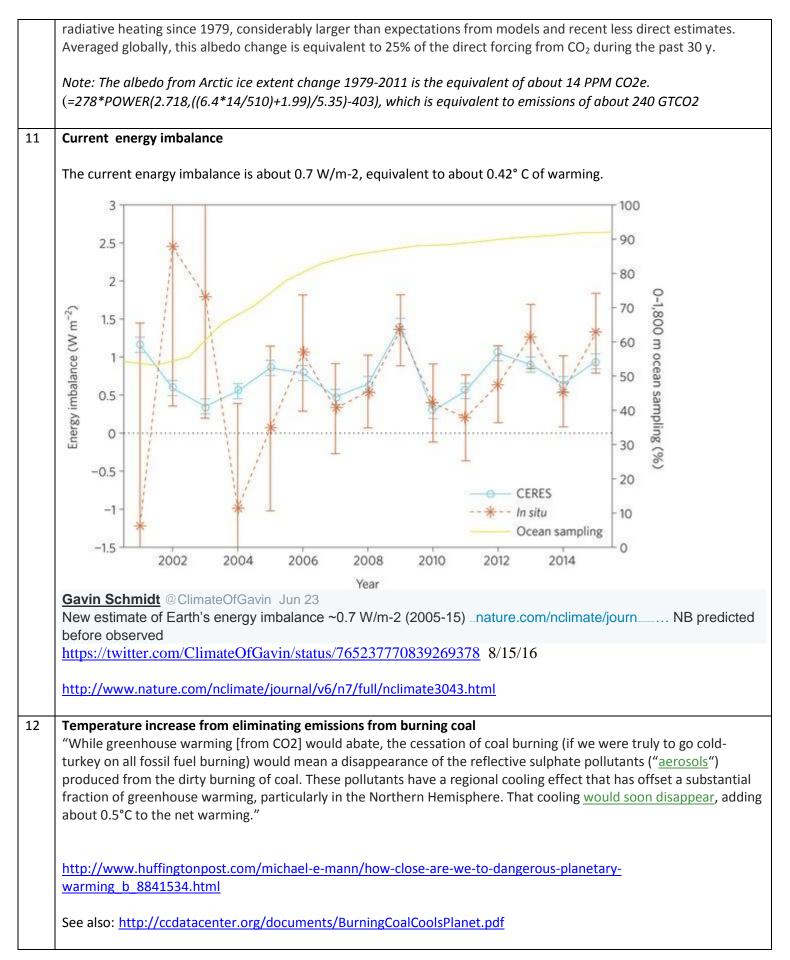

The future costs of CDR are very difficult to predict. In the recently published book "Climate Intervention – Carbon Dioxide Removal and Reliable Sequestration" the National Resource Council (NRC) estimated costs for "bio-energy with carbon capture and storage" (BECCS) at about \$100/ton CO2 and for "direct air capture" (DAC) at \$400-\$1000/ton CO2 (Table 2.2 in the report). Other CDR methods are available but may also be of little use given the magnitude of the problem. Due to the likely limited availability land for of BECCS and because of the really large quantities of CO2 that must be removed, DAC removal will likely need to be used most widely.

Assuming some progress in the coming years, a reasonable CCS cost between now and 2055 might be \$50/ton CO2 (which can be used for future fossil fuel emissions).

Given both the amount of CO2 that needs to be removed (over 2000 GTCO2) and the rate of capture for the various alternatives, BECCS and DAC are the only viable alternatives for CDR. And given the limitations of land for BECCS, DAC is the only method that captures CO2 in the needed quantities. Assuming technological advances, if DAC costs can be reduced by a factor of four, costs later this century might be \$100/ton CO2.

(What would be really important to determine is the energy requirement to compress the captured CO2 and compress it. It should then be possible to estimate the number of "power plant equivalents" to compress and sequester annually 1 PPM of the atmospheric CO2.)

	CDR Method	Rate of Capture or Sequestration [GtCO ₂ /yr]	Cumulative CDR to 2100 [GtCO ₂]	Cost [\$/tCO ₂]		Limitations

Widespread thawing of the permafrost								
"The <u>new research</u> suggests that based on what's happened in the Earth's past, global temperatures 1.5 degrees Celsius above pre-industrial levels could cause vast areas of carbon-rich permafrost to thaw."								
https://www.carbonbrief.org/new-research-projects-widespread-permafrost-thaw-with-1-5-degrees-of-warming								
"It's certainly not much of a stretch of the imagination to think that over the coming decades, we could lose a couple of gigatons [of carbon] per year from thawing permafrost," says Holmes. <u>https://www.washingtonpost.com/news/energy-environment/wp/2015/04/01/the-arctic-climate-threat-that- nobodys-even-talking-about-yet/</u>								
If only a small fraction of Arctic carbon is released into the atmosphere the result could be catastrophic								
"Even if a small fraction of the Arctic carbon were released to the atmosphere, we're fucked," Dr Jason Box								
http://motherboard.vice.com/read/if-we-release-a-small-fraction-of-arctic-carbon-were-fucked-climatologist								
Climate Impacts vs. Temperature Increase In the chart below, Caldeira and his colleagues graphed the extent of damage from climate change on								
various sectors of the environment. They found that the sensitivity of some of these categories to small increases in temperature will be highest within the first several degrees of warming, and then tapers off, having hit a physical limit, or what the researchers call a "saturation of impacts," as in the case of coral reefs at two degrees Celsius. Once the planet gets into the higher degrees of warming, the rate of impact begins to plateau—because there won't be anything left to be affected. 1.0 0.8 0.8 0.8 0.8 0.8 0.8 0.8 0.8 0.8 0

0.0 0 1 2 3 4 5 6 Global Temperature Change (°C) Some climate change impacts rise fast with little warming, and then taper off, write a team of researchers in a paper published during the 2015 Paris climate talks. RICKE ET AL/NATURE GEOSCIENCE http://www.newsweek.com/earth-resources-ruined-two-degrees-warming-threshold-404406								

16	Sea Level Rise
	Looking the geologic record, sea level rise has typically been about 10– 20 m/°C. Given that we are currently committed to at least a 2°C temperature increase, the long-term sea level rise will likely be at least 20 meters (over 60 feet) <u>http://ccdatacenter.org/documents/Sea%20Level%20Rise.pdf</u>
17	Ocean Acidification
	"We are now carrying out an extraordinary chemical experiment on a global scale. Our fossil-fuel emissions raise the dissolved CO ₂ levels in the ocean, which reduces carbonate ion concentrations and lowers pH. The ocean's sunlit surface layer (the top 100 yards or so) could easily lose 50 percent of its carbonate ion by the end of this century unless we reduce emissions dramatically. Marine animals will find it harder to build skeletons, construct reefs, or simply to grow and breathe. Compared with past geologic events, the speed and scale of this conversion is astonishing." http://www.scientificamerican.com/article/rising-acidity-in-the-ocean/
